

# Package ‘diagis’

November 29, 2021

**Type** Package

**Title** Diagnostic Plot and Multivariate Summary Statistics of Weighted Samples from Importance Sampling

**Version** 0.2.2

**Description** Fast functions for effective sample size, weighted multivariate mean, variance, and quantile computation, and weight diagnostic plot for generic importance sampling type or other probability weighted samples.

**License** GPL (>= 2)

**BugReports** <https://github.com/helske/diagis/issues>

**URL** <https://github.com/helske/diagis/>

**Suggests** covr, knitr, rmarkdown, testthat,

**Imports** coda, ggplot2 (>= 2.1.0), gridExtra, Rcpp (>= 0.12.7)

**LinkingTo** Rcpp, RcppArmadillo

**RoxygenNote** 7.1.2

**VignetteBuilder** knitr

**Encoding** UTF-8

**NeedsCompilation** yes

**Author** Jouni Helske [aut, cre] (<<https://orcid.org/0000-0001-7130-793X>>)

**Maintainer** Jouni Helske <jouni.helske@iki.fi>

**Repository** CRAN

**Date/Publication** 2021-11-29 16:10:02 UTC

diagis	<i>Auxiliary functions and diagnostic plots for importance sampling</i>
--------	---

---

## Description

This package contains functions computing weighted (running) summaries and diagnostic plots for importance sampling problems.

## Examples

```
# simple importance sampling example
# true distribution is a standard normal:
p <- function(x) dnorm(x)
# proposal distribution is normal with sd s
q <- function(x, s) dnorm(x, 0, s)

# IS weights have finite variance only if s^2 > 1/2
# variance is s/(2-1/s^2)^(3/2)

#optimal case
set.seed(42)
s_opt <- sqrt(2)
x_opt <- rnorm(1000, sd = s_opt)
w_opt <- p(x_opt) / q(x_opt, s_opt)
weighted_mean(x_opt, w_opt)
weighted_var(x_opt, w_opt)
s_inf <- 0.25
x_inf <- rnorm(1000, sd = s_inf)
w_inf <- p(x_inf) / q(x_inf, s_inf)
weighted_mean(x_inf, w_inf) #!!
weighted_var(x_inf, w_inf) #!!
# diagnostic plots
weight_plot(w_inf)
weight_plot(w_opt)
```

---

ess	<i>Effective sample size</i>
-----	------------------------------

---

**Description**

Computes the effective sample size (ESS) of importance sampling estimator.

**Usage**

```
ess(w, f, x)
```

**Arguments**

w	A numeric vector of non-negative weights.
f	A function used in computing f-specific ESS.
x	A numeric vector of samples used to generate w. Used for computing f(x).

**Value**

An effective sample size estimate.

---

running_ess	<i>Running effective sample size</i>
-------------	--------------------------------------

---

**Description**

Computes and returns the running estimate of effective sample size (ESS) of importance sampling estimator.

**Usage**

```
running_ess(w, f, x)
```

**Arguments**

w	A numeric vector of non-negative weights.
f	A function used in computing f-specific ESS.
x	A numeric vector of samples used to generate w. Used for computing f(x).

**Value**

An effective sample size estimate.

---

running_mean	<i>Running mean</i>
--------------	---------------------

---

**Description**

Computes running mean of a vector or matrix, returning the values from each step.

**Usage**

```
running_mean(x, na.rm)
```

**Arguments**

x	A numeric vector, matrix, three dimensional array, or an mcmc object from the coda package. For matrix, the mean is computed for each column, and for array the sweep is done over the third dimension.
na.rm	If TRUE, NA values in x are omitted from the computation. Default is FALSE.

**Value**

A vector containing the recursive mean estimates.

---

running_var	<i>Running variance of a vector</i>
-------------	-------------------------------------

---

**Description**

Computes running variance of a vector, returning the values from each step.

**Usage**

```
running_var(x, method = c("moment", "unbiased"), na.rm = FALSE)
```

**Arguments**

x	A numeric vector or object that can be coerced to such.
method	Estimator type, either "moment" (default) or "unbiased", which is unbiased only in case of frequency weights.
na.rm	If TRUE, NA values in x are omitted from the computation. Default is FALSE.

**Value**

A vector containing the recursive variance estimates.

---

running\_weighted\_mean *Running weighted mean*

---

**Description**

Computes running weighted mean of a vector or matrix, returning the values from each step.

**Usage**

```
running_weighted_mean(x, w, na.rm)
```

**Arguments**

x	A numeric vector, matrix, three dimensional array, or an mcmc object from the coda package. For matrix, the mean is computed for each column, and for array the sweep is done over the third dimension.
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
na.rm	If TRUE, NA values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE. Only used in vector methods.

**Value**

A vector containing the recursive weighted mean estimates.

---

running\_weighted\_var *Running weighted variance of a vector*

---

**Description**

Computes running weighted variance of a vector, returning the values from each step.

**Usage**

```
running_weighted_var(x, w, method = c("moment", "unbiased"), na.rm = FALSE)
```

**Arguments**

x	A numeric vector or object that can be coerced to such.
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
method	Estimator type, either "moment" (default) or "unbiased", which is unbiased only in case of frequency weights.
na.rm	If TRUE, NA values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE.

**Value**

A vector containing the recursive weighted variance estimates.

---

weighted_mean	<i>Weighted mean</i>
---------------	----------------------

---

**Description**

Computes a weighted mean of a vector, matrix, or a three dimensional array.

**Usage**

```
weighted_mean(x, w, na.rm)
```

**Arguments**

x	A numeric vector, matrix, three dimensional array, or an mcmc object from the coda package. For matrix, the mean is computed for each column, and for array the sweep is done over the third dimension.
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
na.rm	If TRUE, NA values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE. Only used in vector methods.

**Value**

A weighted mean.

---

weighted_quantile	<i>Weighted quantiles</i>
-------------------	---------------------------

---

**Description**

Computes a weighted quantiles of a vector or matrix. Based on the formula in Wikipedia (see the vignette) which is one of many ways to compute weighted quantiles.

**Usage**

```
weighted_quantile(x, w, probs = probs, na.rm)
```

**Arguments**

x	A numeric vector or matrix. For matrix, the quantiles are computed for each column.
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
probs	A numeric vector of probabilities with values between 0 and 1.
na.rm	If TRUE, NA and NaN values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE. Additional missing values in w are not allowed.

**Value**

A weighted variance.

**Note**

Compared to some other R functions, here the weights are regarded as probability weights, not frequency weights.

---

weighted_se	<i>Weighted standard error</i>
-------------	--------------------------------

---

**Description**

Computes a weighted standard error of a vector or matrix.

**Usage**

```
weighted_se(x, w, na.rm)
```

**Arguments**

x	A numeric vector or matrix. For matrix, standard errors are computed for each column
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
na.rm	If TRUE, NA values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE.

**Value**

A weighted variance.

**Note**

Compared to some other R functions, here the weights are regarded as probability weights, not frequency weights.

---

weighted_var	<i>Weighted covariance</i>
--------------	----------------------------

---

**Description**

Computes a weighted variance/covariance of a vector, matrix or a three dimensional array.

**Usage**

```
weighted_var(x, w, method, na.rm)
```

**Arguments**

x	A numeric vector, matrix or three dimensional array. For matrix, covariances are computed between columns. For array, marginal covariances are computed for each column, i.e. for $m \times n \times k$ array function returns $m \times m \times n$ array.
w	A numeric vector of non-negative weights. Will be automatically normalised to sum to one.
method	Estimator type, either "moment" (default) or "unbiased", which is unbiased only in case of frequency weights.
na.rm	If TRUE, NA values in x (and corresponding weights in w) are omitted from the computation. Default is FALSE.

**Value**

A weighted variance.

**Note**

Compared to some other R functions, here the weights are regarded as probability weights, not frequency weights.

---

weight_plot	<i>Diagnostic plot of importance sampling weights</i>
-------------	---

---

**Description**

Function `weight_plot` plots four figures given the weight vector `w`: Plot of largest weights, sorted graph of all weights, running variance estimate of weights, and running effective sample size estimate of weights.

**Usage**

```
weight_plot(w)
```

**Arguments**

w                    Vector of weights.

**Examples**

```
#' importance sampling from too narrow distribution
#' weights have infinite variance
set.seed(1)
x_inf <- rnorm(1000, sd = 0.1)
w_inf <- dnorm(x_inf) / dnorm(x_inf, 0, 0.1)
weight_plot(w_inf)
x_opt <- rnorm(1000, sd = sqrt(2))
w_opt <- dnorm(x_opt) / dnorm(x_opt, 0, sqrt(2))
weight_plot(w_opt)
```
