

# Package ‘nvmix’

September 10, 2025

**Version** 0.1-2

**Encoding** UTF-8

**Title** Multivariate Normal Variance Mixtures

**Description** Functions for working with (grouped) multivariate normal variance mixture distributions (evaluation of distribution functions and densities, random number generation and parameter estimation), including Student's t distribution for non-integer degrees-of-freedom as well as the grouped t distribution and copula with multiple degrees-of-freedom parameters. See <[doi:10.18637/jss.v102.i02](https://doi.org/10.18637/jss.v102.i02)> for a high-level description of select functionality.

**Author** Marius Hofert [aut, cre],

copula	<i>Functionalities for Normal Variance Mixture Copulas</i>
--------	--

---

## Description

Evaluate the density / distribution function of normal variance mixture copulas (including Student  $t$  and normal copula) and generate vectors of random variates from normal variance mixture copulas.

## Usage

```

dnmixcopula(u, qmix, scale = diag(d), factor = NULL, control = list(),
             verbose = FALSE, log = FALSE, ...)
pnmixcopula(upper, lower = matrix(0, nrow = n, ncol = d), qmix, scale = diag(d),
             control = list(), verbose = FALSE, ...)
rnmixcopula(n, qmix, scale = diag(2), factor = NULL,
             method = c("PRNG", "sobol", "ghalton"), skip = 0,
             control = list(), verbose = FALSE, ...)

dStudentcopula(u, df, scale = diag(d), factor = NULL, log = FALSE, verbose = TRUE)
pStudentcopula(upper, lower = matrix(0, nrow = n, ncol = d), df, scale = diag(d),
               control = list(), verbose = TRUE)
rStudentcopula(n, df, scale = diag(2), method = c("PRNG", "sobol", "ghalton"),
               skip = 0)

pgStudentcopula(upper, lower = matrix(0, nrow = n, ncol = d), groupings = 1:d,
                df, scale = diag(d), control = list(), verbose = TRUE)
dgStudentcopula(u, groupings = 1:d, df, scale = diag(d), factor = NULL,
                factor.inv = NULL, control = list(), verbose = TRUE, log = FALSE)
rgStudentcopula(n, groupings = 1:d, df, scale = diag(2), factor = NULL,
                method = c("PRNG", "sobol", "ghalton"), skip = 0)

fitgStudentcopula(x, u, df.init = NULL, scale = NULL, groupings = rep(1, d),

```

```

df.bounds = c(0.5, 30), fit.method = c("joint-MLE",
"groupwise-MLE"), control = list(), verbose = TRUE)
fitStudentcopula(u, fit.method = c("Moment-MLE", "EM-MLE", "Full-MLE"),
df.init = NULL, df.bounds = c(0.1, 30), control = list(),
verbose = TRUE)

```

## Arguments

u	$(n, d)$ -matrix of evaluation points or data; Have to be in $(0, 1)$ .
upper, lower	$(n, d)$ -matrix of upper/lower evaluation limits. Have to be in $(0, 1)$ .
n	sample size $n$ (positive integer).
qmix	specification of the mixing variable $W$ ; see <code>pnmix()</code> for the ungrouped and <code>pgnvmix()</code> for the grouped case.
groupings	see <code>pgnvmix()</code> .
df	positive degrees of freedom; can also be <code>Inf</code> in which case the copula is interpreted as the Gaussian copula.
scale	scale matrix (a covariance matrix entering the distribution as a parameter) of dimension $(d, d)$ (defaults to $d = 2$ ); this equals the covariance matrix of a random vector following the specified normal variance mixture distribution divided by the expectation of the mixing variable $W$ if and only if the former exists. Note that scale must be positive definite; sampling from singular ungrouped normal variance mixtures can be achieved by providing factor.
factor	$(d, k)$ -matrix such that <code>factor %*% t(factor)</code> equals scale; the non-square case $k \neq d$ can be used to sample from singular normal variance mixtures. For <code>dnmixcopula()</code> , this has to be a square matrix. Note that this notation coincides with McNeil et al. (2015, Chapter 6). If not provided, factor is internally determined via <code>chol()</code> (and multiplied from the right to an $(n, k)$ -matrix of independent standard normals to obtain a sample from a multivariate normal with zero mean vector and covariance matrix scale).
factor.inv	inverse of factor; if not provided, computed via <code>solve(factor)</code> .
method	see <code>rnmix()</code> .
skip	see <code>rnmix()</code> .
df.init	<code>NULL</code> or vector with initial estimates for df; can contain NAs.
df.bounds	2-vector with the lower/upper bounds on the degree-of-freedom parameter for the fitting.
fit.method	character indicating which fitting method is to be used; see details below.
x	$(n, d)$ -matrix data matrix of which the underlying copula is to be estimated. See also details below.
control	list specifying algorithm specific parameters; see <code>get_set_param()</code> .
verbose	logical indicating whether a warning is given if the required precision <code>abstol</code> has not been reached.
log	logical indicating whether the logarithmic density is to be computed.
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>rmix</code> or <code>qmix</code> is a character string or function.

## Details

Functionalities for normal variance mixture copulas provided here essentially call `pnmix()`, `dnvmix()` and `rnmix()` as well as `qnmix()`, see their documentations for more details.

We remark that computing normal variance mixtures is a challenging task; evaluating normal variance mixture copulas additionally requires the approximation of a univariate quantile function so that for large dimensions and sample sizes, these procedures can be fairly slow. As there are approximations on many levels, reported error estimates for the copula versions of `pnmix()` and `dnvmix()` can be flawed.

The functions `[d/p/r]Studentcopula()` are user-friendly wrappers for `[d/p/r]nvmixcopula(qmix = "inverse.gamma")`, designed for the important case of a t copula with degrees-of-freedom `df`.

The function `fitgStudentcopula()` can be used to estimate the matrix scale and the degrees-of-freedom for grouped t-copulas. The matrix scale, if not provided, is estimated non-parametrically. Initial values for the degrees-of-freedom are estimated for each group separately (by fitting the corresponding marginal t copula). Using these initial values, the joint likelihood over all (`length(unique(groupings))`-many) degrees-of-freedom parameters is optimized via `optim()`. For small dimensions, the results are satisfactory but the optimization becomes extremely challenging when the dimension is large, so care should be taking when interpreting the results.

## Value

The values returned by `dnvmixcopula()`, `rnmixcopula()` and `pnmixcopula()` are similar to the ones returned by their non-copula alternatives `dnvmix()`, `rnmix()` and `pnmix()`.

The function `fitgStudentcopula()` returns an S3 object of class `"fitgStudentcopula"`, basically a `list` which contains, among others, the components

`df` Estimated degrees-of-freedom for each group.  
`scale` Estimated or provided scale matrix.  
`max.ll` Estimated log-likelihood at reported estimates.  
`df.init` Initial estimate for the degrees-of-freedom.

The methods `print()` and `summary()` are defined for the class `"fitgStudentcopula"`.

### Examples

```
## Generate a random correlation matrix in d dimensions
d <- 2 # dimension
set.seed(42) # for reproducibility
rho <- runif(1, min = -1, max = 1)
P <- matrix(rho, nrow = d, ncol = d) # build the correlation matrix P
diag(P) <- 1
## Generate two random evaluation points:
u <- matrix(runif(2*d), ncol = d)
## We illustrate using a t-copula
df = 2.1
## Define quantile function which is inverse-gamma here:
qmix. <- function(u) 1/qgamma(1-u, shape = df/2, rate = df/2)

### Example for dnvmixcopula() #####

## If qmix = "inverse.gamma", dnvmix() calls qt and dt:
d1 <- dnvmixcopula(u, qmix = "inverse.gamma", scale = P, df = df)
## Same can be obtained using 'dStudentcopula()'
d2 <- dStudentcopula(u, scale = P, df = df)
stopifnot(all.equal(d1, d2))
## Use qmix. to force the algorithm to use a rqmc procedure:
d3 <- dnvmixcopula(u, qmix = qmix., scale = P)
stopifnot(all.equal(d1, d3, tol = 1e-3, check.attributes = FALSE))

### Example for pnvmixcopula() #####

## Same logic as above:
p1 <- pnvmixcopula(u, qmix = "inverse.gamma", scale = P, df = df)
p2 <- pnvmixcopula(u, qmix = qmix., scale = P)
stopifnot(all.equal(p1, p2, tol = 1e-3, check.attributes = FALSE))

### Examples for rnvmixcopula() #####

## Draw random variates and compare
n <- 60
set.seed(1)
X <- rnvmixcopula(n, qmix = "inverse.gamma", df = df, scale = P) # with scale
```

```

set.seed(1)
X. <- rnmixcopula(n, qmix = "inverse.gamma", df = df, factor = t(chol(P))) # with factor
stopifnot(all.equal(X, X.))

### Example for the grouped case #####

d <- 4 # dimension
set.seed(42) # for reproducibility
P <- matrix(runif(1, min = -1, max = 1), nrow = d, ncol = d) # build the correlation matrix P
diag(P) <- 1
groupings <- c(1, 1, 2, 2) # two groups of size two each
df <- c(1, 4) # dof for each of the two groups
U <- rgStudentcopula(n, groupings = groupings, df = df, scale = P)
(fit <- fitgStudentcopula(u = U, groupings = groupings, verbose = FALSE))

```

---

dependencemeasures      *Dependence Measures for grouped normal variance mixture copulas*

---

## Description

Computation of rank correlation coefficients Spearman's rho and Kendall's tau for grouped normal variance mixture copulas as well as computation of the (lower and upper) tail dependence coefficient of a grouped  $t$  copula.

## Usage

```

corgnvmix(scale, qmix, method = c("kendall", "spearman"), groupings = 1:2,
          ellip.kendall = FALSE, control = list(), verbose = TRUE, ...)

```

```

lambda_gStudent(df, scale, control = list(), verbose = TRUE)

```

## Arguments

scale	<i>n</i> -vector giving the $\rho$ parameters of the copula.
qmix	specification of the mixing variables; see <code>pgnvmix()</code> .
method	character indicating if Spearman's rho or Kendall's tau is to be computed.
groupings	vector specifying the grouping structure; either <code>rep(1, 2)</code> (ungrouped) or <code>1:2</code> (grouped case).
ellip.kendall	logical if the formula for Kendall's tau for elliptical copulas shall be used; see details below.
df	either scalar or 2-vector giving the degrees-of-freedom for the $t$ copula; if provided as scalar, the copula is an (ungrouped) $t$ copula and <code>lambda_gStudent()</code> uses a closed formula.
control	list specifying algorithm specific parameters; see <code>get_set_param()</code> .
verbose	logical indicating whether a warning is given if the required precision has not been reached.

... additional arguments (for example, parameters) passed to the underlying mixing distribution when `qmix` is a [character](#) string or [function](#).

## Details

For grouped normal variance mixture copulas, including the grouped  $t$ , there is no closed formula for Kendall's tau and Spearman's rho. The function `corgnvmix()` approximates these dependence measures by numerically approximating an integral representation for these measures.

If no grouping is present (i.e., when `groupings = rep(1, 2)`), the copula is an elliptical copula for which the formula  $\tau = 2\text{asin}(\rho)/\pi$  holds. This formula holds only approximately in the grouped case; the quality of the approximation depends on how different the mixing variables for the two components are. When the mixing distributions are not too far apart and when the copula parameter is not close to 1, this approximation is "very accurate", as demonstrated in Daul et al (2003).

In the ungrouped case, `lambda_gStudent()` computes the tail dependence coefficient *lambda* based on the known formula  $2 * \text{pt}(-\sqrt{(df + 1) * (1 - \rho) / (1 + \rho)})$ ,  $df = df + 1$ ) for the tail dependence coefficient of a  $t$  copula.

In the grouped case, RQMC methods are used to efficiently approximate the integral given in Eq. (26) of Luo and Shevchenko (2010).

## Value

`lambda_gStudent()` and `corgnvmix()` return a [numeric](#)  $n$ -vector with the computed dependence measure with corresponding attributes "abs. error" and "rel. error" (error estimates of the RQMC estimator) and "numiter" (number of iterations).

    paste0("df1 = ", df_[[i]][1], ", ", df2 = ", df_[[i]][2])
}
legend("topleft", lgnd, col = seq_len(l.df_), lty = seq_len(l.df_),
      bty = 'n')
## If called with 'df' a 1-vector, closed formula for lambda is used => check
lambda.true <- sapply(1:3, function(i) lambda_gStudent(df_[[i]][1], scale = scale))
stopifnot(max(abs( lambda.true - lambdas[, 1:3])) < 4e-4)

```

## Description

Evaluating grouped normal variance mixture density functions (including Student  $t$  with multiple degrees-of-freedom).

## Usage

```
dgnvmix(x, groupings = 1:d, qmix, loc = rep(0, d), scale = diag(d), factor = NULL,
        factor.inv = NULL, control = list(), log = FALSE, verbose = TRUE, ...)
dgStudent(x, groupings = 1:d, df, loc = rep(0, d), scale = diag(d), factor = NULL,
          factor.inv = NULL, control = list(), log = FALSE, verbose = TRUE)
```

## Arguments

<code>x</code>	see <a href="#">dnvmix()</a> .
<code>groupings</code>	see <a href="#">pgnvmix()</a> .
<code>qmix</code>	specification of the mixing variables $W_i$ via quantile functions; see <a href="#">pgnvmix()</a> .
<code>loc</code>	see <a href="#">pnvmix()</a> .
<code>scale</code>	see <a href="#">pnvmix()</a> ; must be positive definite.
<code>factor</code>	$(d, d)$ lower triangular <a href="#">matrix</a> such that <code>factor %*% t(factor)</code> equals <code>scale</code> . Internally used is <code>factor.inv</code> .
<code>factor.inv</code>	inverse of <code>factor</code> ; if not provided, computed via <code>solve(factor)</code> .
<code>df</code>	<a href="#">vector</a> of length <code>length(unique(groupings))</code> so that variable <code>i</code> has degrees-of-freedom <code>df[groupings[i]]</code> ; all elements must be positive and can be <code>Inf</code> , in which case the corresponding marginal is normally distributed.
<code>control</code>	<a href="#">list</a> specifying algorithm specific parameters; see <a href="#">get_set_param()</a> .
<code>log</code>	<a href="#">logical</a> indicating whether the logarithmic density is to be computed.
<code>verbose</code>	see <a href="#">pnvmix()</a> .
<code>...</code>	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <a href="#">character</a> string or an element of <code>qmix</code> is a <a href="#">function</a> .

## Details

Internally used is `factor.inv`, so `factor` and `scale` are not required to be provided (but allowed for consistency with other functions in the package).

`dgStudent()` is a wrapper of `dgnvmix()`, `qmix = "inverse.gamma"`, `df = df`). If there is no grouping, the analytical formula for the density of a multivariate  $t$  distribution is used.

Internally, an adaptive randomized Quasi-Monte Carlo (RQMC) approach is used to estimate the log-density. It is an iterative algorithm that evaluates the integrand at a randomized Sobol' point-set

(default) in each iteration until the pre-specified error tolerance `control$dgnvmix.reltol` in the `control` argument is reached for the log-density. The attribute `"numiter"` gives the worst case number of such iterations needed (over all rows of `x`). Note that this function calls underlying C code.

Algorithm specific parameters (such as above mentioned `control$dgnvmix.reltol`) can be passed as a `list` via the `control` argument, see `get_set_param()` for details and defaults.

If the error tolerance cannot be achieved within `control$max.iter.rqmc` iterations and `fun.eval[2]` function evaluations, an additional warning is thrown if `verbose=TRUE`.

### Value

`dgnvmix()` and `dgStudent()` return a `numeric`  $n$ -vector with the computed density values and corresponding attributes `"abs.error"` and `"rel.error"` (error estimates of the RQMC estimator) and `"numiter"` (number of iterations).

## If 'qmix' provided as string and no grouping, dgnvmix() uses analytical formula
dt2 <- dgnvmix(x, qmix = "inverse.gamma", groupings = groupings, df = df, scale = P, log = TRUE)
stopifnot(all.equal(dt1, dt2))
## Provide 'qmix' as a function to force estimation in 'dgnvmix()'
dt3 <- dgnvmix(x, qmix = qmix_, groupings = groupings, df = df, scale = P, log = TRUE)
stopifnot(all.equal(dt1, dt3, tol = 5e-4, check.attributes = FALSE))

### 2. More complicated mixture

## Let W1 ~ IG(1, 1), W2 = 1, W3 ~ Exp(1), W4 ~ Par(2, 1), W5 = W1, all comonotone
## => X1 ~ t_2; X2 ~ normal; X3 ~ Exp-mixture; X4 ~ Par-mixture; X5 ~ t_2

d <- 5
set.seed(157)
A <- matrix(runif(d * d), ncol = d)
P <- cov2cor(A %*% t(A))
b <- 3 * runif(d) * sqrt(d) # random upper limit
groupings <- c(1, 2, 3, 4, 1) # since W_5 = W_1
qmix <- list(function(u) qmix_(u, df = 2), function(u) rep(1, length(u)),
            list("exp", rate=1), function(u) (1-u)^(-1/2)) # length 4 (# of groups)
x <- rgnvmix(n, groupings = groupings, qmix = qmix, scale = P)
dg <- dgnvmix(x, groupings = groupings, qmix = qmix, scale = P, log = TRUE)

```

dnvmix

*Density of Multivariate Normal Variance Mixtures***Description**

Evaluating multivariate normal variance mixture densities (including Student  $t$  and normal densities).

**Usage**

```
dnvmix(x, qmix, loc = rep(0, d), scale = diag(d),
       factor = NULL, control = list(), log = FALSE, verbose = TRUE, ...)

dStudent(x, df, loc = rep(0, d), scale = diag(d), factor = NULL,
         log = FALSE, verbose = TRUE, ...)
dNorm(x, loc = rep(0, d), scale = diag(d), factor = NULL,
      log = FALSE, verbose = TRUE, ...)
```

**Arguments**

<code>x</code>	$(n, d)$ -matrix of evaluation points.
<code>qmix</code>	specification of the mixing variable $W$ ; see <code>pnmix()</code> for details and examples.
<code>df</code>	positive degrees of freedom; can also be <code>Inf</code> in which case the distribution is interpreted as the multivariate normal distribution with mean vector <code>loc</code> and covariance matrix <code>scale</code> .
<code>loc</code>	location vector of dimension $d$ ; this equals the mean vector of a random vector following the specified normal variance mixture distribution if and only if the latter exists.
<code>scale</code>	scale matrix (a covariance matrix entering the distribution as a parameter) of dimension $(d, d)$ ; this equals the covariance matrix of a random vector following the specified normal variance mixture distribution divided by the expectation of the mixing variable $W$ if and only if the former exists. Needs to be full rank for the density to exist.
<code>factor</code>	$(d, d)$ lower triangular matrix such that <code>factor %*% t(factor)</code> equals <code>scale</code> ; note that for performance reasons, this property is not tested. If not provided, <code>factor</code> is internally determined via <code>t(chol())</code> .
<code>control</code>	list specifying algorithm specific parameters; see <code>get_set_param()</code> .
<code>log</code>	logical indicating whether the logarithmic density is to be computed.
<code>verbose</code>	logical indicating whether a warning is given if the required precision <code>abstol</code> has not been reached.
<code>...</code>	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a character string or function.

## Details

For the density to exist, scale must be full rank. Internally used is factor, so scale is not required to be provided if factor is given. The default factorization used to obtain factor is the Cholesky decomposition via `chol()`.

`dStudent()` and `dNorm()` are wrappers of `dnvmix(, qmix = "inverse.gamma", df = df)` and `dnvmix(, qmix = "constant")`, respectively. In these cases, `dnvmix()` uses the analytical formulas for the density of a multivariate Student  $t$  and normal distribution, respectively.

Internally, an adaptive randomized Quasi-Monte Carlo (RQMC) approach is used to estimate the log-density. It is an iterative algorithm that evaluates the integrand at a randomized Sobol' point-set (default) in each iteration until the pre-specified error tolerance `control$dnvmix.reltol` in the control argument is reached for the log-density. The attribute "numiter" gives the worst case number of such iterations needed (over all rows of `x`). Note that this function calls underlying C code.

Algorithm specific parameters (such as above mentioned `control$dnvmix.reltol`) can be passed as a `list` via the control argument, see `get_set_param()` for details and defaults.

If the error tolerance cannot be achieved within `control$max.iter.rqmc` iterations and `fun.eval[2]` function evaluations, an additional warning is thrown if `verbose=TRUE`.

## Value

`dnvmix()`, `dStudent()` and `dNorm()` return a `numeric`  $n$ -vector with the computed (log-)density values and attributes "abs. error" and "rel. error" (containing the absolute and relative error estimates of the of the (log-)density) and "numiter" (containing the number of iterations).

```

## Description

Functionalities for fitting multivariate normal variance mixtures (in particular also Multivariate  $t$  distributions) via an ECME algorithm.

## Usage

```
fitnvmix(x, qmix, mix.param.bounds, nu.init = NA, loc = NULL, scale = NULL,
         init.size.subsample = min(n, 100), size.subsample = n,
         control = list(), verbose = TRUE)
```

```
fitStudent(x, loc = NULL, scale = NULL, mix.param.bounds = c(1e-3, 1e2), ...)
fitNorm(x)
```

## Arguments

<code>x</code>	$(n, d)$ -data <b>matrix</b> .
<code>qmix</code>	specification of the mixing variable $W$ ; see McNeil et al. (2015, Chapter 6). Supported are the following types of specification (see also the examples below): <b>character:</b> <b>character</b> string specifying a supported distribution; currently available are "constant" (in which case $W = 1$ and thus the multivariate normal distribution with mean vector <code>loc</code> and covariance matrix <code>scale</code> results), "inverse.gamma" (in which case $W$ is inverse gamma distributed with shape and rate parameters <code>df/2</code> and thus the multivariate Student $t$ distribution with <code>df</code> degrees of freedom results) and "pareto" (in which case $W$ is Pareto distributed with scale equal to unity and shape equal to <code>alpha</code> ). <b>function:</b> <b>function</b> interpreted as the quantile function of the mixing variable $W$ . In this case, <code>qmix</code> <i>must</i> have the form <code>qmix = function(u, nu)</code> , where the argument <code>nu</code> corresponds to the parameter (vector) specifying the distribution of the mixing variable.
<code>mix.param.bounds</code>	either <b>numeric</b> (2) or a <b>matrix</b> with two columns. The first/second column corresponds to the lower/upper bound of $nu_i$ , the $i$ th component of the parameter vector $nu$ of the mixing variable $W$ . All elements need to be finite, numeric values. Note: The algorithm tends to converge quicker if the parameter ranges supplied are smaller.
<code>nu.init</code>	either NA or an initial guess for the parameter (vector) $nu$ . In the former case an initial estimate is calculated by the algorithm. If <code>nu.init</code> is provided, the algorithm often converges faster; the better the starting value, the faster convergence.
<code>loc</code>	<b><math>d</math>-vector</b> ; if provided, taken as the 'true' location vector in which case <code>loc</code> is not estimated.
<code>scale</code>	positive definite $(d, d)$ - <b>matrix</b> ; if provided, taken as the 'true' scale matrix in which case <code>scale</code> is not estimated.
<code>init.size.subsample</code>	<b>numeric</b> , non-negative, giving the sub-samplesize used to get an initial estimate for $nu$ . Only used if <code>is.na(nu.init)</code> , otherwise ignored.

size.subsample	<b>numeric</b> , non-negative, specifying the size of the subsample that is being used in the ECME iterations to optimize the log-likelihood over $nu$ . Defaults to $n$ , so that the full sample is being used. Decreasing this number can lead to faster run-times (as fewer log-densities need to be estimated) but also to an increase in bias and variance.
control	<b>list</b> specifying algorithm specific parameters; see below under 'Details' and <code>get_set_param()</code> .
verbose	<b>numeric</b> or <b>logical</b> (in which case it is converted to <b>numeric</b> ) specifying the amount of tracing to be done. If $0$ or <b>FALSE</b> , neither tracing nor warnings are communicated; if $1$ , only warnings are communicated, if $2$ or $3$ , warnings and (shorter or longer) tracing information is provided.
...	additional arguments passed to the underlying <code>fitnvmix()</code> .

### Details

The function `fitnvmix()` uses an ECME algorithm to approximate the MLEs of the parameters  $nu$ ,  $loc$  and  $scale$  of a normal variance mixture specified by `qmix`. The underlying procedure successively estimates  $nu$  (with given  $loc$  and  $scale$ ) by maximizing the likelihood which is approximated by `dnvmix()` (unless `qmix` is a character string, in which case analytical formulas for the log-densities are used) and  $scale$  and  $loc$  (given  $nu$ ) using weights (which again need to be approximated) related to the posterior distribution, details can be found in the first reference below.

It should be highlighted that (unless `qmix` is a character string), every log-likelihood and every weight needed in the estimation is numerically approximated via RQMC methods. For large dimensions and sample sizes this procedure can therefore be slow.

Various tolerances and convergence criteria can be changed by the user via the `control` argument. For more details, see `get_set_param()`.

### Value

The function `fitnvmix()` returns an S3 object of **class** "fitnvmix", basically a **list** which contains, among others, the components

- `nu` Estimated mixing parameter (vector)  $nu$ .
- `loc` Estimated or provided  $loc$  vector.
- `scale` Estimated or provided  $scale$  matrix.
- `max.ll` Estimated log-likelihood at reported estimates.
- `x` Input data matrix  $x$ .

The methods `print()`, `summary()` and `plot()` are defined for the class "fitnvmix".

`fitStudent()` is a wrapper to `fitnvmix()` for parameter estimation of multivariate Student  $t$  distributions; it also returns an S3 object of **class** "fitnvmix" where the fitted degrees of freedom are called "df" instead of "nu" (to be consistent with the other wrappers for the Student  $t$  distributions).

`fitNorm()` just returns a **list** with components `loc` (columnwise sample means) and `scale` (sample covariance matrix).

qmix <- function(u, nu) (1-u)^(-1/nu)
## Sample data using 'rnmix':
x <- rnmix(n, qmix = qmix, nu = nu, loc = loc, scale = scale)
## Call 'fitnvmix' with 'qmix' as function (=> densities/weights estimated)
(MyFit21 <- fitnvmix(x, qmix = qmix, mix.param.bounds = mix.param.bounds))
## Call 'fitnvmix' with 'qmix = "pareto"' in which case an analytical formula
## for the density is used
(MyFit22 <- fitnvmix(x, qmix = "pareto", mix.param.bounds = mix.param.bounds))
stopifnot(all.equal(MyFit21$nu, MyFit22$nu, tol = 5e-2))

```

gammamix

*Functionalities for Gamma Scale Mixture Models***Description**

Evaluating density-, distribution- and quantile-function of Gamma scale mixtures as well as random variate generation.

**Usage**

```

dgammamix(x, qmix, d, control = list(), verbose = TRUE, log = FALSE, ...)
pgammamix(x, qmix, d, lower.tail = TRUE, control = list(), verbose = TRUE, ...)
qgammamix(u, qmix, d, control = list(), verbose = TRUE, q.only = TRUE,
  stored.values = NULL, ...)
rgammamix(n, rmix, qmix, d, method = c("PRNG", "sobol", "ghalton"),
  skip = 0, ...)

```

**Arguments**

x	<i>n</i> -vector of evaluation points.
u	<i>n</i> -vector of probabilities.
qmix	see <code>pnvmix()</code> .
rmix	see <code>rnmix()</code> .
d	dimension of the underlying normal variance mixture, see also details below.
n	sample size <i>n</i> (positive integer).
lower.tail	<b>logical</b> ; if TRUE (default), probabilities are $P(X \leq x)$ , otherwise $P(X > x)$ .
log	<b>logical</b> indicating whether the log-density shall be returned.

q.only	see <a href="#">qnvmix()</a> .
stored.values	see <a href="#">qnvmix()</a> .
method	see <a href="#">rnmix()</a> .
skip	see <a href="#">rnmix()</a> .
control	<a href="#">list</a> specifying algorithm specific parameters; see <a href="#">get_set_param()</a> .
verbose	<a href="#">logical</a> indicating whether a warning is given if the required precision has not been reached.
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <a href="#">character</a> string or <a href="#">function</a> .

## Details

We define a Gamma mixture as a random variable  $Dsq$  satisfying, in distribution,  $Dsq = W * Gamma(d/2, 2)$  where  $W$  is specified via `qmix`. If  $X$  follows a  $d$ -dimensional normal variance mixture, the squared Mahalanobis distance  $(X - \mu)^T Sigma^{-1}(X - \mu)$  has the same distribution as  $Dsq$ .

The functions presented here are similar to the corresponding functions for normal variance mixtures (`d/p/q/rnmix()`), details can be found in the corresponding help-files there.

## Value

`pgammamix()` and `dgammamix()` return a [numeric](#)  $n$ -vector with the computed probabilities/densities and corresponding attributes "abs. error" and "rel. error" (error estimates of the RQMC estimator) and "numiter" (number of iterations).

If `q.only = TRUE`, `qgammamix()` a vector of the same length as `u` with entries  $q_i$  where  $q_i$  satisfies  $q_i = \inf_x F(x) \geq u_i$  where  $F(x)$  the df of the Gamma mixture specified via `qmix`; if `q.only = FALSE`, see [qnvmix](#).

`rgammamix()` returns a [n-vector](#) containing  $n$  samples of the specified (via `mix`) Gamma mixture.

                    check.attributes = FALSE))
```

---

get\_set\_param

*Algorithm-specific Parameters*

---

## Description

Algorithm specific parameters for functionalities in the `nvmix` package, notably for `fitnvmix()`, `dnvmix()`, `pnvmix()`, `qnvmix()`, `pgamnamix()`, `dgamnamix()` and `ES_nvmix()` as well as the corresponding functions for grouped mixtures.

**Usage**

```
get_set_param(control = list())
```

**Arguments**

control            **list** specifying algorithm specific parameters to beset; see below under details.

**Details**

For most functions in the `nvmix` package, internally, an iterative randomized Quasi-Monte Carlo (RQMC) approach is used to estimate probabilities, weights and (log-)densities. There are various parameters of underlying methods than can be changed.

Algorithm specific parameters can be passed as a list via `control`. It can contain any of the following:

**For all algorithms:** method **character** string indicating the method to be used to compute the integral. Available are:

"sobol": Sobol' sequence (default),

"ghalton": generalized Halton sequence,

"PRNG": plain Monte Carlo based on a pseudo-random number generator.

increment **character** string indicating how the sample size should be increased in each iteration. Available are:

"doubling": next iteration has as many sample points as all the previous iterations combined,

"num.init": all iterations use an additional `fun.eval[1]`-many points (default for most functions).

`CI.factor` multiplier of the Monte Carlo confidence interval bounds. The algorithm runs until `CI.factor` times the estimated standard error is less than `abstol` or `reltol` (whichever is provided). If `CI.factor = 3.5` (the default), one can expect the actual absolute error to be less than `abstol` in 99.9% of the cases.

`fun.eval` **numeric**(2) providing the size of the first point set to be used to estimate integrals (typically a power of 2) and the maximal number of function evaluations. `fun.eval` defaults to `c(2^7, 1e12)`.

`max.iter.rqmc` **numeric**, providing the maximum number of iterations allowed in the RQMC approach; the default is 15 if `increment = "doubling"` and 1250 otherwise.

`B` number of randomizations for obtaining an error estimate in the RQMC approach; the default is 15.

**For `pnmix()` and `pgnvmix()`:** `pnmix.abstol`, `pnmix.reltol` non-negative **numeric** providing the relative/absolute precision required for the distribution function. Relative precision via `pnmix.reltol` is only used when `pnmix.abstol = NA`; in all other cases, absolute precision will be used. `pnmix.abstol` defaults to `1e-3`. If `pnmix.abstol = 0` and `pnmix.reltol = 0`, the algorithm will typically run until the total number of function evaluations exceeds `fun.eval[2]` or until the total number of iterations exceeds `max.iter.rqmc`, whichever happens first. If  $n > 1$  (so upper has more than one row), the algorithm runs until the precision requirement is reached for all  $n$  probability estimates.

mean.sqrt.mix expectation of the square root  $\sqrt{(W)}$  of the mixing variable  $W$ . If NULL, it will be estimated via QMC; this is only needed for determining the reordering of the integration bounds, so a rather crude approximation is fine.

precond **logical** indicating whether preconditioning is applied, that is, reordering of the integration variables. If TRUE, integration limits lower, upper as well as scale are internally re-ordered in a way such that the overall variance of the integrand is usually smaller than with the original ordering; this usually leads smaller run-times.

cholesky.tol non-negative numeric providing lower threshold for non-zero elements in the computation of the cholesky factor: If calculated  $C(i, i)^2 < |cholesky.tol * Scale(i, i)|$ , the diagonal element (and all other elements in column  $i$ ) of the cholesky factor  $C$  are set to zero, yielding a singular matrix. cholesky.tol defaults to 1e-9.

- For** dnmix() and dgnvmix(): dnmix.reltol, dnmix.abstol non-negative **numeric** providing the relative/absolute precision for the \*log-\* density required. Absolute precision via dnmix.abstol is only used when dnmix.reltol = NA; in all other cases, relative precision will be used. dnmix.reltol defaults to 1e-2. If dnmix.reltol=0 and dnmix.abstol=0, the algorithm will typically run until the total number of function evaluations exceeds fun.eval[2] or until the total number of iterations exceeds max.iter.rqmc, whichever happens first. If  $n > 1$  (so  $x$  has more than one row), the algorithm runs until the precision requirement is reached for all  $n$  log-density estimates.
- dnmix.doAdapt **logical** indicating if an adaptive integration procedure shall be used that only samples in relevant subdomains of the mixing variable; defaults to TRUE.
- dnmix.max.iter.rqmc.pilot **numeric**, providing the maximum number of unstratified, non-adaptive pilot runs the internal integration procedure performs. Defaults to 6.
- dnmix.tol.int.lower, dnmix.order.lower both **numeric** and nonnegative. RQMC integration is only performed where the integrand is  $>$  than the maximum of dnmix.tol.int.lower and  $10^{-c}g_{max}$ , where  $g_{max}$  is the theoretical maximum of the integrand and  $c$  is the specified dnmix.order.lower. Default to 1e-100 and 5, respectively.
- dnmix.tol.bisec **numeric** vector of length 3 specifying bisection tolerances in the adaptive RQMC algorithm. First/second/third element specify the tolerance on  $u$ ,  $W$  and the log-integrand and default to 1e-6, 1e-1 and 1e-1, respectively.
- dnmix.max.iter.bisec **numeric**, maximum number of iterations in the internal bisection procedure to find good cutting points allowed, defaults to 15.
- dnmix.tol.stratlength **numeric**, nonnegative. If the stratum found by the adaptive integration method has length  $>$  dnmix.tol.stratlength RQMC integration is used there; otherwise a crude approximation. Defaults to 1e-50.
- For** fitnvmix(): ECMEstep **logical**, if TRUE (default), ECME iteration is performed; if FALSE, no ECME step is performed so that fitnvmix() performs between zero and two optimizations over  $nu$ , depending on laststep.do.nu and whether nu.init was provided.
- ECMEstep.do.nu **logical**, if TRUE (default), the likelihood is maximized over  $nu$  in each ECME iteration; if FALSE, this step is omitted.
- laststep.do.nu **logical**, if TRUE another last maximization of the likelihood over  $nu$  is performed using all observations after the ECME iterations. Only makes sense if either ECMEstep.do.nu=FALSE or if size.subsample is smaller than the number of observations. Defaults to FALSE.
- resample **logical**, if TRUE, a different subsample of  $x$  is taken in each optimization over  $nu$  in the ECME iterations. Only relevant when size.subsample is smaller than the number of observations. Defaults to FALSE.

ECME.miniter, ECME.maxiter **numeric** positive, minimum and maximum number of ECME iterations. Default to 5 and 200, respectively.

max.iter.locscaleupdate **numeric** positive. Maximum number of location-scale updates (while holding *nu* fixed) in each individual ECME iteration; defaults to 50.

weights.reltol **numeric** non-negative. Relative tolerance to estimate internal weights used to update *loc* and *scale* estimates in the ECME iterations. Defaults to 1e-2.

weights.interpol.reltol **numeric** non-negative. Some weights can be obtained by interpolating previously calculated weights; if the maximal relative interpolation error is smaller than `weights.interpol.reltol`, this is done. Defaults to 1e-2.

ECME.rel.conv.tol **numeric**(3) vector specifying relative convergence tolerances for *loc*, *scale* and *nu* (in this order). Defaults to `c(1e-2, 1e-2, 1e-3)`.

control.optim **list** of control parameters passed to the underlying `optim` in the initial step as well as in the ECME iterations. See `optim()` for details; defaults to `list(maxit=75)`.

control.optim.laststep like `control.optim`; this list of control arguments is passed to `optim` in the last-step. Only relevant when `laststep.do.nu = TRUE` and defaults to `list()` (so no defaults of `optim()` changed).

**For** `qnvmix()`: `max.iter.newton` **numeric**, maximum number of Newton iterations allowed to approximate the quantile; defaults to 45.

`newton.conv.abstol` **numeric**, convergence tolerance for the Newton procedure; convergence is detected once the difference of estimated quantiles in two successive iterations is smaller than `newton.conv.abstol`; defaults to 5e-4.

`newton.df.reltol` **numeric**, relative error tolerance for estimating the univariate distribution function; defaults to 2.5e-4.

`newton.logdens.abstol` **numeric**, absolute error tolerance for the internal estimation of the log-density needed for the update; defaults to 1e-2.

`newton.df.max.iter.rqmc` **numeric**, maximum number of iterations to estimate the univariate distribution function required in the Newton update; defaults to 350. Note that internally used is `increment = "doubling"`, no matter what.

**For** `qqplot_maha()`: `qqplot.df.reltol` **numeric**, with the same meaning as `newton.df.reltol` for the function `qnvmix()`. Defaults to 5e-3.

**For** `ES_nvmix()`: `riskmeasures.abstol`, `riskmeasures.reltol` **numeric**, absolute or relative error tolerance for estimating riskmeasures, notably for `ES_nvmix()`. By default, `riskmeasures.reltol=5e-2` and `riskmeasures.abstol=NA`, so that a relative tolerance is used.

Care should be taken when changing algorithm specific parameters, notably tolerances, as the accuracy of the result is heavily influenced by those.

## Value

`get_set_param()` returns a **list** with more than 30 elements specifying algorithm specific parameters for the functions `fitnvmix()`, `dnavmix()`, `pnvmix()`, `qnvmix()`, `pgammamix()`, `dammamix()` and `ES_nvmix()`, as well as the corresponding functions for grouped mixtures such as `pgnvmix()` and `dgnvmix()`. Parameter values passed to `get_set_param()` via the `control` argument overwrite the defaults; for parameters not specified in the `control` argument, the default values are being returned.

```

---

get\_set\_qqplot\_param *Plotting parameters for QQ Plots*

---

**Description**

Plotting parameters for the method `plot()` of the class `qqplot_maha`.

**Usage**

```
get_set_qqplot_param(plot.pars = list(log = ""))
```

**Arguments**

`plot.pars` [list](#) specifying plotting parameters to be set; see below under details.

**Details**

This function provides a convenient way to set plotting parameters in the argument `plot.pars` of the function `qqplot_maha()` (more precisely, the underlying `plot()` method), such as logarithmic plotting, colors, linetypes and more.

The input list `plot.pars` can contain any of the following:

`log` [character](#) specifying the logarithmic axes. Just like for the generic `plot`, must be one of "", "x", "y" or "xy".

`xlim`, `ylim` The x- and y-limits for plotting.

`xlab`, `ylab` [character](#) specifying the x- and y-axis labels. Default to "Theoretical quantiles" and "Sample quantiles", respectively.

sub, main **character** specifying title and subtitle of the plot; default to "", so no titles.

plot\_legend, plot\_test, plot\_line **logical** specifying if a legend should be plotted; if the test result of the GoF test should be displayed on the 3rd axis and if the plot should contain a fitted line. All default to TRUE.

pch specification of the plotting symbol; see `?points()`. Defaults to 1.

lty **3-vector** containing the specification of the linetypes for i) the diagonal, ii) the asymptotic CI and iii) the bootstrap CI; see also `?par()`. Defaults to 1:3.

col **4-vector** specifying the colors to be used for i) the points in the QQ plot; ii) the diagonal; iii) the asymptotic CI and iv) the bootstrap CI. Defaults to `c("black", "red", "azure4", "chocolate4")`.

### Value

`get_set_qqplot_param()` returns a **list** with 13 elements that is passed to `qqplot_maha()`, more specifically, to the underlying `plot()` method. Parameter values passed to `get_set_qqplot_param()` via the `plot.pars` argument overwrite the defaults; for parameters not specified in the `plot.pars` argument, the default values are being returned.

---

numerical\_experiments\_data

*Data Generated by the Demo 'numerical\_experiments'*

---

### Description

Data generated by the `demo('numerical_experiments')` of the `nvmix` package.

### Usage

```
data(numerical_experiments_data, package = "nvmix")
```

**Format**

A list with 10 elements:

`$pnmix.abserrors` Array as returned by the function `pnmix_testing_abserr()`, see Section 1.1 of the demo('numerical\_experiments').

`$pnmix.t.variances` Array as returned by the function `precond_testing_variance()`, see Section 1.1 of the demo('numerical\_experiments').

`$pnmix.t.sobolind` Array as returned by the function `pnmix_estimate_sobolind()`, see Section 1.1 of the demo('numerical\_experiments').

`$pnmix.t.timing` Array as returned by the function `pnmix_timing_mvt()`, see Section 1.1 of the demo('numerical\_experiments').

`$dnvmix.results` Array as returned by the function `dnvmix_testing()`, see Section 1.2 of the demo('numerical\_experiments').

`$fitnvmix.results` Array as returned by the function `fitnvmix_testing()`, see Section 1.3 of the demo('numerical\_experiments').

`$fit.dj30.analytical` Array containing results of `fitnvmix()` applied to DJ30 data using analytical weights/densities, see Section 5 of demo('numerical\_experiments').

`$fit.dj30.estimated` Array containing results of `fitnvmix()` applied to DJ30 data using estimated weights/densities, see Section 5 of demo('numerical\_experiments').

`$qqplots.dj30` Array containing results of `qqplot.maha()` applied to DJ30 data, see Section 5 of the demo('numerical\_experiments').

`$tailprobs.dj30` Array containing estimated quantile shortfall probabilities of models fitted to DJ30 data, see Section 5 of demo('numerical\_experiments').

pgnvmix	<i>Distribution Function of Grouped Multivariate Normal Variance Mixtures</i>
---------	---

---

**Description**

Evaluating grouped and generalized multivariate normal variance mixture distribution functions (including Student  $t$  with multiple degrees-of-freedom).

**Usage**

```
pgnvmix(upper, lower = matrix(-Inf, nrow = n, ncol = d), groupings = 1:d, qmix,
        rmix, loc = rep(0, d), scale = diag(d), standardized = FALSE,
        control = list(), verbose = TRUE, ...)
```

```
pgStudent(upper, lower = matrix(-Inf, nrow = n, ncol = d), groupings = 1:d, df,
          loc = rep(0, d), scale = diag(d), standardized = FALSE,
          control = list(), verbose = TRUE)
```

**Arguments**

upper	see <code>pnmix()</code> .
lower	see <code>pnmix()</code> .
groupings	<i>d</i> -vector. Specification of the groupings so that variable $i$ has mixing variable $W_k$ where $k = \text{groupings}[i]$ . If <code>groupings = 1:d</code> , each variable has a different mixing distribution.
qmix	specification of the mixing variables $W_i$ via quantile functions; see McNeil et al. (2015, Chapter 6) and Hintz et al. (2020). Supported are the following types of specification (see also the examples below): <ul style="list-style-type: none"> <li><b>character:</b> <code>character</code> string specifying a supported distribution; currently available are "inverse.gamma" (in which case <math>W_i</math> is inverse gamma distributed with shape and rate parameters <math>\text{df}[\text{groupings}[i]]/2</math> and a multivariate Student <math>t</math> distribution multiple degrees-of-freedom results) and "pareto" (in which case <math>W_i</math> is Pareto distributed with scale equal to unity and shape equal to <math>\text{alpha}[\text{groupings}[i]]</math>. <code>alpha</code> and <code>df</code> must be of length <math>\text{length}(\text{unique}(\text{groupings}))</math> and need to be provided via the <code>ellipsis</code> argument).</li> <li><b>list:</b> <code>list</code> of length <math>\text{length}(\text{unique}(\text{groupings}))</math> (number of different mixing distributions). Element <math>i</math> of this list specifies the mixing variable for component <code>groupings[i]</code>. Each element of this list can be <ul style="list-style-type: none"> <li><b>list:</b> a <code>list</code> of length at least one, where the first component is a <code>character</code> string specifying the base name of a distribution whose quantile function can be accessed via the prefix "q". An example "exp" for which "qexp" exists. If the list is of length larger than one, the remaining elements contain additional parameters of the distribution; for "exp", for example, this can be the parameter rate.</li> <li><b>function:</b> <code>function</code> interpreted as the quantile function or random number generator of the mixing variable <math>W_i</math></li> </ul> </li> </ul>
rmix	only allowed when <code>groupings = rep(1, d)</code> in which case <code>pgnvmix()</code> is equivalent to <code>pnmix()</code> ; see <code>pnmix()</code> .
df	<code>vector</code> of length $\text{length}(\text{unique}(\text{groupings}))$ so that variable $i$ has degrees-of-freedom $\text{df}[\text{groupings}[i]]$ ; all elements must be positive and can be <code>Inf</code> , in which case the corresponding marginal is normally distributed.
loc	see <code>pnmix()</code> .
scale	see <code>pnmix()</code> ; must be positive definite.
standardized	see <code>pnmix()</code> .
control	<code>list</code> specifying algorithm specific parameters; see <code>get_set_param()</code> .
verbose	see <code>pnmix()</code> .
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <code>character</code> string or an element of <code>qmix</code> is a <code>function</code> .

## Details

One should highlight that evaluating grouped normal variance mixtures is a non-trivial task which, at the time of development of `nvmix`, was not available in R before, not even the special case of a multivariate Student  $t$  distribution for non-integer degrees of freedom, which frequently appears in applications in finance, insurance and risk management after estimating such distributions.

Internally, an iterative randomized Quasi-Monte Carlo (RQMC) approach is used to estimate the probabilities. It is an iterative algorithm that evaluates the integrand at a point-set (with size as specified by `control$increment` in the `control` argument) in each iteration until the pre-specified absolute error tolerance `control$pgnvmix.abstol` (or relative error tolerance `control$pgnvmix.reltol` which is used only when `control$pgnvmix.abstol = NA`) is reached. The attribute `"numiter"` gives the number of such iterations needed. Algorithm specific parameters (such as the above mentioned `control$pgnvmix.abstol`) can be passed as a list via `control`, see `get_set_param()` for more details. If specified error tolerances are not reached and `verbose = TRUE`, a warning is thrown.

`pgStudent()` is a wrapper of `pgnvmix(, qmix = "inverse.gamma", df = df)`.

## Value

`pgnvmix()` and `pgStudent()` return a `numeric`  $n$ -vector with the computed probabilities and corresponding attributes `"abs. error"` and `"rel. error"` (error estimates of the RQMC estimator) and `"numiter"` (number of iterations).

### Examples for pgnvmix() #####

## 1. Inverse-gamma mixture (=> distribution is grouped t with mutliple dof)
d <- 3
set.seed(157)
A <- matrix(runif(d * d), ncol = d)
P <- cov2cor(A %% t(A))
a <- -3 * runif(d) * sqrt(d) # random lower limit
b <- 3 * runif(d) * sqrt(d) # random upper limit
df <- c(1.1, 2.4, 4.9) # dof for margin i
groupings <- 1:d

### Call 'pgnvmix' with 'qmix' a string:
set.seed(12)
(pgt1 <- pgnvmix(b, lower = a, groupings = groupings, qmix = "inverse.gamma",
                 df = df, scale = P))

### Version providing quantile functions of the mixing distributions as list
qmix_ <- function(u, df) 1 / qgamma(1-u, shape = df/2, rate = df/2)
qmix <- list(function(u) qmix_(u, df = df[1]), function(u) qmix_(u, df = df[2]),
             function(u) qmix_(u, df = df[3]))

set.seed(12)
(pgt2 <- pgnvmix(b, lower = a, groupings = groupings, qmix = qmix, scale = P))
### Similar, but using ellipsis argument:
qmix <- list(function(u, df1) qmix_(u, df1), function(u, df2) qmix_(u, df2),
             function(u, df3) qmix_(u, df3))

set.seed(12)
(pgt3 <- pgnvmix(b, lower = a, groupings = groupings, qmix = qmix,
                 scale = P, df1 = df[1], df2 = df[2], df3 = df[3]))
## Version using the user friendly wrapper 'pgStudent()'
set.seed(12)
(pgt4 <- pgStudent(b, lower = a, groupings = groupings, scale = P, df = df))
stopifnot(all.equal(pgt1, pgt2, tol = 1e-4, check.attributes = FALSE),
          all.equal(pgt2, pgt3), all.equal(pgt1, pgt4))

## 2. More complicated mixutre
## Let W1 ~ IG(1, 1), W2 = 1, W3 ~ Exp(1), W4 ~ Par(2, 1), W5 = W1, all comonotone
## => X1 ~ t_2; X2 ~ normal; X3 ~ Exp-mixture; X4 ~ Par-mixture; X5 ~ t_2

d <- 5
set.seed(157)
A <- matrix(runif(d * d), ncol = d)
P <- cov2cor(A %% t(A))
b <- 3 * runif(d) * sqrt(d) # random upper limit
groupings <- c(1, 2, 3, 4, 1) # since W_5 = W_1
qmix <- list(function(u) qmix_(u, df = 2), function(u) rep(1, length(u)),
             list("exp", rate=1), function(u) (1-u)^(-1/2)) # length 4 (# of groups)
pg1 <- pgnvmix(b, groupings = groupings, qmix = qmix, scale = P)
stopifnot(all.equal(pg1, 0.78711, tol = 5e-6, check.attributes = FALSE))

```

pnmix

*Distribution Function of Multivariate Normal Variance Mixtures***Description**

Evaluating multivariate normal variance mixture distribution functions (including Student  $t$  and normal distributions).

**Usage**

```
pnmix(upper, lower = matrix(-Inf, nrow = n, ncol = d), qmix, rmix,
      loc = rep(0, d), scale = diag(d), standardized = FALSE,
      control = list(), verbose = TRUE, ...)

pStudent(upper, lower = matrix(-Inf, nrow = n, ncol = d), df, loc = rep(0, d),
         scale = diag(d), standardized = FALSE, control = list(), verbose = TRUE)
pNorm(upper, lower = matrix(-Inf, nrow = n, ncol = d), loc = rep(0, d),
      scale = diag(d), standardized = FALSE, control = list(), verbose = TRUE)
```

**Arguments**

**upper**  $(n, d)$ -**matrix** of upper integration limits; each row represents a  $d$ -vector of upper integration limits.

**lower**  $(n, d)$ -**matrix** of lower integration limits (componentwise less than or equal to upper); each row represents a  $d$ -vector of lower integration limits.

**qmix, rmix** specification of the mixing variable  $W$  via a quantile function (**qmix**) (recommended, see details below) \*or\* random number generator (**rmix**); see McNeil et al. (2015, Chapter 6) and Hintz et al. (2020). Supported are the following types of specification (see also the examples below):

**character:** **character** string specifying a supported distribution; currently available are "constant" (in which case  $W = 1$  and thus the multivariate normal distribution with mean vector **loc** and covariance matrix **scale** results), "inverse.gamma" (in which case  $W$  is inverse gamma distributed with shape and rate parameters  $df/2$  and thus the multivariate Student  $t$  distribution with  $df$  degrees of freedom (required to be provided via the **ellipsis** argument) results) and "pareto" (in which case  $W$  is Pareto distributed with scale equal to unity and shape equal to  $\alpha$ , which needs to be provided via the **ellipsis** argument).

**list:** **list** of length at least one, where the first component is a **character** string specifying the base name of a distribution whose quantile function or random number generator can be accessed via the prefix "q" and "r", respectively. an example is "exp" for which "qexp" exists. If the list is of length larger than one, the remaining elements contain additional parameters of the distribution; for "exp", for example, this can be the parameter rate.

	<b>function:</b> <code>function</code> interpreted as the quantile function or random number generator of the mixing variable $W$ .
<code>df</code>	positive degrees of freedom; can also be <code>Inf</code> in which case the distribution is interpreted as the multivariate normal distribution with mean vector <code>loc</code> and covariance matrix <code>scale</code> .
<code>loc</code>	location vector of dimension $d$ ; this equals the mean vector of a random vector following the specified normal variance mixture distribution if and only if the latter exists.
<code>scale</code>	scale matrix (a covariance matrix entering the distribution as a parameter) of dimension $(d, d)$ ; this equals the covariance matrix of a random vector following the specified normal variance mixture distribution divided by the expectation of the mixing variable $W$ if and only if the former exists. <code>scale</code> is allowed to be singular in which case the distribution function of the singular normal variance mixture is returned.
<code>standardized</code>	logical indicating whether <code>scale</code> is assumed to be a correlation matrix.
<code>control</code>	<code>list</code> specifying algorithm specific parameters; see <code>get_set_param()</code> .
<code>verbose</code>	<code>logical</code> indicating whether a warning is thrown if the required precision <code>pnvmix.abstol</code> or <code>pnvmix.reltol</code> as specified in the <code>control</code> argument has not been reached; can also be an <code>integer</code> in which case 0 is FALSE, 1 is TRUE and 2 stands for producing a more verbose warning (for each set of provided integration bounds).
<code>...</code>	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <code>character</code> string or <code>function</code> .

## Details

One should highlight that evaluating normal variance mixtures is a non-trivial task which, at the time of development of **nmix**, was not available in R before, not even the special case of a multivariate Student  $t$  distribution for non-integer degrees of freedom, which frequently appears in applications in finance, insurance and risk management after estimating such distributions.

Note that the procedures call underlying C code. Currently, dimensions  $d \geq 16510$  are not supported for the default method `sobol`.

Internally, an iterative randomized Quasi-Monte Carlo (RQMC) approach is used to estimate the probabilities. It is an iterative algorithm that evaluates the integrand at a point-set (with size as specified by `control$increment` in the `control` argument) in each iteration until the pre-specified absolute error tolerance `control$pnvmix.abstol` (or relative error tolerance `control$pnvmix.reltol` which is used only when `control$pnvmix.abstol = NA`) is reached. The attribute `"numiter"` gives the number of such iterations needed. Algorithm specific parameters (such as the above mentioned `control$pnvmix.abstol`) can be passed as a list via `control`, see `get_set_param()` for more details. If specified error tolerances are not reached and `verbose = TRUE`, a warning is thrown.

If provided `scale` is singular, `pnvmix()` estimates the correct probability but throws a warning if `verbose = TRUE`.

It is recommended to supply a quantile function via `qmix`, if available, as in this case efficient RQMC methods are used to approximate the probability. If `rmix` is provided, internally used is plain MC integration, typically leading to slower convergence. If both `qmix` and `rmix` are provided, the latter is ignored.

pStudent() and pNorm() are wrappers of pnmix(, qmix = "inverse.gamma", df = df) and pnmix(, qmix = "constant"), respectively. In the univariate case, the functions pt() and pnorm() are used.

### Value

pnmix(), pStudent() and pNorm() return a numeric  $n$ -vector with the computed probabilities and corresponding attributes "abs. error" and rel. error (error estimates of the RQMC estimator) and "numiter" (number of iterations).

## Here is a version providing the quantile function of the mixing distribution
qmix <- function(u, df) 1 / qgamma(1-u, shape = df/2, rate = df/2)
mean.sqrt.mix <- sqrt(df) * gamma(df/2) / (sqrt(2) * gamma((df+1) / 2))
set.seed(123)
pt2 <- pnvmix(b, lower = a, qmix = qmix, df = df, scale = P,
             control = list(mean.sqrt.mix = mean.sqrt.mix))

## Compare
stopifnot(all.equal(pt1, pt2, tol = 7e-4, check.attributes = FALSE))

## mean.sqrt.mix will be approximated by QMC internally if not provided,
## so the results will differ slightly.
set.seed(123)
pt3 <- pnvmix(b, lower = a, qmix = qmix, df = df, scale = P)
stopifnot(all.equal(pt3, pt1, tol = 7e-4, check.attributes = FALSE))

## Here is a version providing a RNG for the mixing distribution
## Note the significantly larger number of iterations in the attribute 'numiter'
## compared to when 'qmix' was provided (=> plain MC versus RQMC)
set.seed(123)
pt4 <- pnvmix(b, lower = a,
             rmix = function(n, df) 1/rgamma(n, shape = df/2, rate = df/2),
             df = df, scale = P)
stopifnot(all.equal(pt4, pt1, tol = 8e-4, check.attributes = FALSE))

## Case with missing data and a matrix of lower and upper bounds
a. <- matrix(rep(a, each = 4), ncol = d)
b. <- matrix(rep(b, each = 4), ncol = d)
a.[2,1] <- NA
b.[3,2] <- NA
pt <- pnvmix(b., lower = a., qmix = "inverse.gamma", df = df, scale = P)
stopifnot(is.na(pt) == c(FALSE, TRUE, TRUE, FALSE))

## Case where upper = (Inf,...,Inf) and lower = (-Inf,...,-Inf)
stopifnot(all.equal(pnvmix(upper = rep(Inf, d), qmix = "constant"), 1,
                  check.attributes = FALSE))

## An example with singular scale:
A <- matrix( c(1, 0, 0, 0,
              2, 1, 0, 0,
              3, 0, 0, 0,
              4, 1, 0, 1), ncol = 4, nrow = 4, byrow = TRUE)
scale <- A%*%t(A)
upper <- 2:5

pn <- pnvmix(upper, qmix = "constant", scale = scale) # multivariate normal
pt <- pnvmix(upper, qmix = "inverse.gamma", scale = scale, df = df) # multivariate t

stopifnot(all.equal(pn, 0.8581, tol = 1e-3, check.attributes = FALSE))
stopifnot(all.equal(pt, 0.7656, tol = 1e-3, check.attributes = FALSE))

## Evaluate a Exp(1)-mixture

```

```

## Specify the mixture distribution parameter
rate <- 1.9 # exponential rate parameter

## Method 1: Use R's qexp() function and provide a list as 'mix'
set.seed(42)
(p1 <- pnvmix(b, lower = a, qmix = list("exp", rate = rate), scale = P))

## Method 2: Define the quantile function manually (note that
##           we do not specify rate in the quantile function here,
##           but conveniently pass it via the ellipsis argument)
set.seed(42)
(p2 <- pnvmix(b, lower = a, qmix = function(u, lambda) -log(1-u)/lambda,
              scale = P, lambda = rate))

## Check
stopifnot(all.equal(p1, p2))

### Examples for pStudent() and pNorm() #####

## Evaluate a t_{3.5} distribution function
set.seed(271)
pt <- pStudent(b, lower = a, df = 3.5, scale = P)
stopifnot(all.equal(pt, 0.6180, tol = 7e-5, check.attributes = FALSE))

## Evaluate a normal distribution function
set.seed(271)
pn <- pNorm(b, lower = a, scale = P)
stopifnot(all.equal(pn, 0.7001, tol = 1e-4, check.attributes = FALSE))

## pStudent deals correctly with df = Inf:
set.seed(123)
p.St.dfInf <- pStudent(b, df = Inf, scale = P)
set.seed(123)
p.Norm <- pNorm(b, scale = P)
stopifnot(all.equal(p.St.dfInf, p.Norm, check.attributes = FALSE))

```

---

qnvmix

*Quantile Function of a univariate Normal Variance Mixture Distribution*

---

## Description

Evaluating multivariate normal variance mixture distribution functions (including normal and Student  $t$  for non-integer degrees of freedom).

## Usage

```

qnvmix(u, qmix, control = list(),
       verbose = TRUE, q.only = TRUE, stored.values = NULL, ...)

```

**Arguments**

<code>u</code>	vector of probabilities .
<code>qmix</code>	specification of the mixing variable $W$ ; see <code>pnmix()</code> for details and examples.
<code>control</code>	<a href="#">list</a> specifying algorithm specific parameters; see <code>get_set_param()</code> .
<code>verbose</code>	<a href="#">logical</a> , if TRUE a warning is printed if one of the error tolerances is not met.
<code>q.only</code>	<a href="#">logical</a> . If TRUE, only the quantiles are returned; if FALSE, see Section 'value' below.
<code>stored.values</code>	<a href="#">matrix</a> with 3 columns of the form $[x, F(x), \log f(x)]$ where $F()$ and $\log f()$ are the distribution- and log-density function of the distribution specified in <code>qmix</code> . If provided it is used to determine starting values for internal newton procedures. Only very basic checking is done.
<code>...</code>	additional arguments containing parameters of mixing distributions when <code>qmix</code> is a <a href="#">character</a> string.

**Details**

This function uses a Newton procedure to estimate the quantile of the specified univariate normal variance mixture distribution. Internally, a randomized quasi-Monte Carlo (RQMC) approach is used to estimate the distribution and (log)density function; the method is similar to the one in `pnmix()` and `dnmix()`. The result depends slightly on `.random.seed`.

Internally, symmetry is used for  $u \leq 0.5$ . Function values (i.e., df and log-density values) are stored and reused to get good starting values. These values are returned if `q.only = FALSE` and can be re-used by passing it to `qnvmix()` via the argument `stored.values`; this can significantly reduce run-time.

Accuracy and run-time depend on both the magnitude of  $u$  and on how heavy the tail of the underlying distributions is. Numerical instabilities can occur for values of  $u$  close to 0 or 1, especially when the tail of the distribution is heavy.

If `q.only = FALSE` the log-density values of the underlying distribution evaluated at the estimated quantiles are returned as well: This can be useful for copula density evaluations where both quantities are needed.

Underlying algorithm specific parameters can be changed via the `control` argument, see `get_set_param()` for details.

**Value**

If `q.only = TRUE` a vector of the same length as `u` with entries  $q_i$  where  $q_i$  satisfies  $q_i = \inf_x F(x) \geq u_i$  where  $F(x)$  the univariate df of the normal variance mixture specified via `qmix`;

if `q.only = FALSE` a list of four:

`$q`: Vector of quantiles,

`$log.density`: vector log-density values at `q`,

`$computed.values`: matrix with 3 columns  $[x, F(x), \log f(x)]$ ; see details above,

`$newton.iterations`: vector giving the number of Newton iterations needed for `u[i]`.

**Examples**

```
## Evaluation points
u <- seq(from = 0.05, to = 0.95, by = 0.025)
set.seed(271) # for reproducibility

## Evaluate the t_{1.4} quantile function
df <- 1.4
qmix. <- function(u) 1/qgamma(1-u, shape = df/2, rate = df/2)
## If qmix = "inverse.gamma", qt() is being called
qt1 <- qnvmix(u, qmix = "inverse.gamma", df = df)
## Estimate quantiles (without using qt())
qt1. <- qnvmix(u, qmix = qmix., q.only = FALSE)
stopifnot(all.equal(qt1, qt1.$q, tolerance = 2.5e-3))
## Look at absolute error:
abs.error <- abs(qt1 - qt1.$q)
plot(u, abs.error, type = "l", xlab = "u", ylab = "Absolute error")
## Now do this again but provide qt1.$stored.values, in which case at most
## one Newton iteration will be needed:
qt2 <- qnvmix(u, qmix = qmix., stored.values = qt1.$computed.values, q.only = FALSE)
stopifnot(max(qt2$newton.iterations) <= 1)
```

**Description**

Visual goodness-of-fit test for multivariate normal variance mixtures: Plotting squared Mahalanobis distances against their theoretical quantiles.

**Usage**

```
qqplot_maha(x, qmix, loc, scale, fitnvmix_object,
            trafo.to.normal = FALSE, test = c("KS.AD", "KS", "AD", "none"),
            boot.pars = list(B = 500, level = 0.95),
            plot = TRUE, verbose = TRUE, control = list(),
            digits = max(3, getOption("digits") - 4), plot.pars = list(), ...)
```

**Arguments**

<code>x</code>	<code>(n, d)</code> -data <a href="#">matrix</a> .
<code>qmix</code>	see <a href="#">pnvmix()</a> .
<code>loc</code>	see <a href="#">pnvmix()</a> .
<code>scale</code>	see <a href="#">pnvmix()</a> .
<code>fitnvmix_object</code>	Optional. Object of class "fitnvmix" typically returned by <a href="#">fitnvmix()</a> ; if provided, <code>x</code> , <code>qmix</code> , <code>loc</code> and <code>scale</code> are ignored.
<code>trafo.to.normal</code>	<a href="#">logical</a> . If TRUE, the underlying Mahalanobis distances are mapped to normals by a probability-quantile-transform so that the resulting QQ plot is essentially a normal QQ plot. Defaults to FALSE.
<code>test</code>	<a href="#">character</a> specifying if (and which) GoF test shall be performed. "KS" performs a Kolmogorov-Smirnoff (see <a href="#">ks.test()</a> ), "AD" an Anderson-Darling test (see <a href="#">ad.test()</a> from the package <code>ADGofTest</code> and "none" performs no test. By default, <code>test = "KS.AD"</code> in which case both tests are performed.
<code>boot.pars</code>	<a href="#">list</a> with elements <code>B</code> (Bootstrap sample size for computing CIs; if <code>B &lt;= 1</code> , no Bootstrap is performed) and <code>level</code> specifying the confidence level.
<code>plot</code>	<a href="#">logical</a> specifying if the results should be plotted.
<code>verbose</code>	see <a href="#">pnvmix()</a> .
<code>control</code>	see <a href="#">get_set_param()</a> .
<code>digits</code>	integer specifying the number of digits of the test statistic and the p-value to be displayed.
<code>plot.pars</code>	<a href="#">list</a> specifying plotting parameters such as logarithmic axes; see <a href="#">get_set_qqplot_param()</a> .
<code>...</code>	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <a href="#">character</a> string or <a href="#">function</a> .

**Details**

If  $X$  follows a multivariate normal variance mixture, the distribution of the Mahalanobis distance  $D^2 = (X - \mu)^T \Sigma^{-1} (X - \mu)$  is a gamma mixture whose distribution function can be approximated.

The function `qqplot_maha()` first estimates the theoretical quantiles by calling [qgammamix\(\)](#) and then plots those against the empirical squared Mahalanobis distances from the data in `x` (with  $\mu = \text{loc}$  and  $\Sigma = \text{scale}$ ). Furthermore, the function computes asymptotic standard errors of the sample quantiles by using an asymptotic normality result for the order statistics which are used to plot the asymptotic CI; see Fox (2008, p. 35 – 36).+

If `boot.pars$B > 1` (which is the default), the function additionally performs Bootstrap to construct a CI. Note that by default, the plot contains both the asymptotic and the Bootstrap CI.

Finally, depending on the parameter `test`, the function performs a univariate GoF test of the observed Mahalanobis distances as described above. The test result (i.e., the value of the statistic along with a p-value) are typically plotted on the second y-axis.

The return object of class "qqplot\_maha" contains all computed values (such as p-value, test-statistics, Bootstrap CIs and more). We highlight that storing this return object makes the QQ plot quickly reproducible, as in this case, the theoretical quantiles do not need to be recomputed.

For changing plotting parameters (such as logarithmic axes or colors) via the argument `plot.pars`, see `get_set_qqplot_param()`.

### Value

`qqplot_maha()` (invisibly) returns an object of the class "qqplot\_maha" for which the methods `plot()` and `print()` are defined. The return object contains, among others, the components

`maha2` Sorted, squared Mahalanobis distances of the data from `loc` wrt to scale.

`theo_quant` The theoretical quantile function evaluated at `ppoints(length(maha2))`.

`boot_CI` ( $2, \text{length}(maha2)$ ) matrix containing the Bootstrap CIs for the empirical quantiles.

`asymptSE` **vector** of length `length(maha2)` with estimated, asymptotic standard errors for the empirical quantiles.

```
## Sample from a heavy tailed multivariate t and construct QQ plot
set.seed(1)
d <- 2
n <- 1000
df <- 3.1
rho <- 0.5
loc <- rep(0, d)
```

```

scale <- matrix(c(1, rho, rho, 1), ncol = 2)
qmix <- "inverse.gamma"
## Sample data
x <- rnvmix(n, qmix = qmix, loc = loc, scale = scale, df = df)
# Construct QQ Plot with 'true' parameters and store result object
qq1 <- qqplot_maha(x, qmix = qmix, df = df, loc = loc, scale = scale)
## ... which is an object of class "qqplot_maha" with two methods
stopifnot(class(qq1) == "qqplot_maha", "plot.qqplot_maha" %in% methods(plot),
           "print.qqplot_maha" %in% methods(print))
plot(qq1) # reproduce the plot
plot(qq1, plotpars = list(log = "xy")) # we can also plot on log-log scale

## In fact, with the 'plotpars' argument, we can change a lot of things
plot(qq1, plotpars = list(col = rep("black", 4), lty = 4:6, pch = "*",
                          plot_test = FALSE, main = "Same with smaller y limits",
                          sub = "MySub", xlab = "MyXlab", ylim = c(0, 1.5e3)))

## What about estimated parameters?
myfit <- fitStudent(x)
## We can conveniently pass 'myfit', rather than specifying 'x', 'loc', ...
set.seed(1)
qq2.1 <- qqplot_maha(fitnvmix_object = myfit, test = "AD", trafo_to_normal = TRUE)
set.seed(1)
qq2.2 <- qqplot_maha(x, qmix = "inverse.gamma", loc = myfit$loc,
                    scale = myfit$scale, df = myfit$df,
                    test = "AD", trafo_to_normal = TRUE)
stopifnot(all.equal(qq2.1$boot_CI, qq2.2$boot_CI)) # check
qq2.2 # it mentions here that the Maha distances were transformed to normal

## Another example where 'qmix' is a function, so quantiles are internally
## estimated via 'qgammamix()'
n <- 15 # small sample size to have examples run fast
## Define the quantile function of an IG(nu/2, nu/2) distribution
qmix <- function(u, df) 1 / qgamma(1 - u, shape = df/2, rate = df/2)
## Sample data
x <- rnvmix(n, qmix = qmix, df = df, loc = loc, scale = scale)
## QQ Plot of empirical quantiles vs true quantiles, all values estimated
## via RQMC:
set.seed(1)
qq3.1 <- qqplot_maha(x, qmix = qmix, loc = loc, scale = scale, df = df)
## Same could be obtained by specifying 'qmix' as string in which case
## qqplot_maha() calls qf()
set.seed(1)
qq3.2 <- qqplot_maha(x, qmix = "inverse.gamma", loc = loc, scale = scale, df = df)

```

## Description

Generate vectors of random variates from grouped normal variance mixtures (including Student  $t$  with multiple degrees-of-freedom).

## Usage

```
rgnvmix(n, qmix, groupings = 1:d, loc = rep(0, d), scale = diag(2),
        factor = NULL, method = c("PRNG", "sobol", "ghalton"), skip = 0, ...)
rgStudent(n, groupings = 1:d, df, loc = rep(0, d), scale = diag(2),
          factor = NULL, method = c("PRNG", "sobol", "ghalton"), skip = 0)
```

## Arguments

n	sample size $n$ (positive integer).
qmix	specification of the mixing variables $W_i$ ; see <a href="#">pgnvmix()</a> .
groupings	<a href="#">vector</a> specifying the group structure; see <a href="#">pgnvmix()</a> .
df	<a href="#">vector</a> specifying the degrees-of-freedom; see <a href="#">pgStudent()</a> .
loc	see <a href="#">pgnvmix()</a> .
scale	see <a href="#">pgnvmix()</a> . scale must be positive definite; sampling from singular normal variance mixtures can be achieved by providing <code>factor</code> .
factor	see <a href="#">rnvmix()</a> .
method	see <a href="#">rnvmix()</a> .
skip	see <a href="#">rnvmix()</a> .
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>qmix</code> is a <a href="#">character</a> string or an element of <code>qmix</code> is a <a href="#">function</a> .

## Details

Internally used is `factor`, so `scale` is not required to be provided if `factor` is given.

The default factorization used to obtain `factor` is the Cholesky decomposition via [chol\(\)](#). To this end, `scale` needs to have full rank.

`rgStudent()` is a wrapper of `rgnvmix(, qmix = "inverse.gamma", df = df)`.

## Value

`rgnvmix()` returns an  $(n, d)$ -[matrix](#) containing  $n$  samples of the specified (via `qmix`)  $d$ -dimensional grouped normal variance mixture with location vector `loc` and scale matrix `scale` (a covariance matrix).

`rgStudent()` returns samples from the  $d$ -dimensional multivariate  $t$  distribution with multiple degrees-of-freedom specified by `df`, location vector `loc` and scale matrix `scale`.

```

**Description**

Estimation of value-at-risk and expected shortfall for univariate normal variance mixtures

**Usage**

```
VaR_nvmix(level, qmix, loc = 0, scale = 1, control = list(), verbose = TRUE, ...)
ES_nvmix(level, qmix, loc = 0, scale = 1, control = list(), verbose = TRUE, ...)
```

**Arguments**

level	<i>n</i> -vector of confidence levels.
qmix	see <code>pnvmix()</code> .
loc	numeric location, see also <code>pnvmix()</code>
scale	numeric scale, see also <code>pnvmix()</code>
control	list specifying algorithm specific parameters; see <code>get_set_param()</code> .
verbose	logical indicating whether a warning is given if the required precision has not been reached.
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when qmix is a character string or function, see also <code>pnvmix()</code>

**Details**

VaR\_nvmix calls `qnvmix()`.

The function `ES_nvmix()` estimates the expected shortfall using a randomized quasi Monte Carlo procedure by sampling from the mixing variable specified via `qmix` and using the identity  $\int_k^\infty x\phi(x)dx = \phi(k)$  where  $\phi(x)$  denotes the density of a standard normal distribution. Algorithm specific parameters (such as tolerances) can be conveniently passed via the `control` argument, see `get_set_param()` for more details.

**Value**

`VaR_nvmix()` and `ES_nvmix()` return a numeric *n*-vector with the computed risk measures and in case of `ES_nvmix()` corresponding attributes "abs. error" and "rel. error" (error estimates of the RQMC estimator) and "numiter" (number of iterations).

---

rnmix	<i>(Quasi-)Random Number Generation for Multivariate Normal Variance Mixtures</i>
-------	---

---

## Description

Generate vectors of random variates from multivariate normal variance mixtures (including Student  $t$  and normal distributions).

## Usage

```
rnmix(n, rmix, qmix, loc = rep(0, d), scale = diag(2),
  factor = NULL, method = c("PRNG", "sobol", "ghalton"),
  skip = 0, ...)

rStudent(n, df, loc = rep(0, d), scale = diag(2), factor = NULL,
  method = c("PRNG", "sobol", "ghalton"), skip = 0)
rNorm(n, loc = rep(0, d), scale = diag(2), factor = NULL,
  method = c("PRNG", "sobol", "ghalton"), skip = 0)
rNorm_sumconstr(n, weights, s, method = c("PRNG", "sobol", "ghalton"), skip = 0)
```

## Arguments

n	sample size $n$ (positive integer).
rmix	specification of the mixing variable $W$ , see McNeil et al. (2015, Chapter 6) and Hintz et al. (2020), via a random number generator. This argument is ignored for method = "sobol" and method = "ghalton". Supported are the following types of specification (see also the examples below): <b>character:</b> <b>character</b> string specifying a supported distribution; currently available are "constant" (in which case $W = 1$ and thus a sample from the multivariate normal distribution with mean vector loc and covariance matrix scale results) and "inverse.gamma" (in which case $W$ is inverse gamma distributed with shape and rate parameters $df/2$ and thus the multivariate Student $t$ distribution with $df$ degrees of freedom (required to be provided via the ellipsis argument) results).

	<p><b>list:</b> <code>list</code> of length at least one, where the first component is a <code>character</code> string specifying the base name of a distribution which can be sampled via prefix "r"; an example is "exp" for which "rexp" exists for sampling. If the list is of length larger than one, the remaining elements contain additional parameters of the distribution; for "exp", for example, this can be the parameter rate.</p> <p><b>function:</b> <code>function</code> interpreted as a random number generator of the mixing variable <math>W</math>; additional arguments (such as parameters) can be passed via the ellipsis argument.</p> <p><b>numeric:</b> <code>numeric</code> vector of length <math>n</math> providing a random sample of the mixing variable <math>W</math>.</p>
qmix	<p>specification of the mixing variable <math>W</math> via a quantile function. This argument is required for <code>method = "sobol"</code> and <code>method = "ghalton"</code>. Supported are the following types of specification (see also the examples below):</p> <p><b>character:</b> <code>character</code> string specifying a supported distribution; currently available are "constant" (in which case <math>W = 1</math> and thus a sample from the multivariate normal distribution with mean vector <code>loc</code> and covariance matrix <code>scale</code> results) and "inverse.gamma" (in which case <math>W</math> is inverse gamma distributed with shape and rate parameters <code>df/2</code> and thus the multivariate Student <math>t</math> distribution with <code>df</code> degrees of freedom (required to be provided via the ellipsis argument) results).</p> <p><b>list:</b> <code>list</code> of length at least one, where the first component is a <code>character</code> string specifying the base name of a distribution which can be sampled via prefix "q"; an example is "exp" for which "qexp" exists for sampling. If the list is of length larger than one, the remaining elements contain additional parameters of the distribution; for "exp", for example, this can be the parameter rate.</p> <p><b>function:</b> <code>function</code> interpreted as the quantile function of the mixing variable <math>W</math>; internally, sampling is then done with the inversion method by applying the provided function to <math>U(0,1)</math> random variates.</p>
df	positive degree of freedom; can also be <code>Inf</code> in which case the distribution is interpreted as the multivariate normal distribution with mean vector <code>loc</code> and covariance matrix <code>scale</code> ).
loc	location vector of dimension $d$ ; this equals the mean vector of a random vector following the specified normal variance mixture distribution if and only if the latter exists.
scale	scale matrix (a covariance matrix entering the distribution as a parameter) of dimension $(d, d)$ (defaults to $d = 2$ ); this equals the covariance matrix of a random vector following the specified normal variance mixture distribution divided by the expectation of the mixing variable $W$ if and only if the former exists. Note that <code>scale</code> must be positive definite; sampling from singular normal variance mixtures can be achieved by providing <code>factor</code> .
factor	$(d, k)$ -matrix such that <code>factor %*% t(factor)</code> equals <code>scale</code> ; the non-square case $k \neq d$ can be used to sample from singular normal variance mixtures. Note that this notation coincides with McNeil et al. (2015, Chapter 6). If not provided, <code>factor</code> is internally determined via <code>chol()</code> (and multiplied from the

	right to an $(n, k)$ -matrix of independent standard normals to obtain a sample from a multivariate normal with zero mean vector and covariance matrix <code>scale</code> ).
method	<code>character</code> string indicating the method to be used to obtain the sample. Available are: "PRNG": pseudo-random numbers, "sobol": Sobol' sequence, "ghalton": generalized Halton sequence. If <code>method = "PRNG"</code> , either <code>qmix</code> or <code>rmix</code> can be provided. If both are provided, <code>rmix</code> is used and <code>qmix</code> ignored. For the other two methods, sampling is done via inversion, hence <code>qmix</code> has to be provided and <code>rmix</code> is ignored.
skip	<code>integer</code> specifying the number of points to be skipped when <code>method = "sobol"</code> , see also example below.
weights	<code>d-numeric</code> vector of weights.
s	<code>numeric</code> vector of length 1 or <code>n</code> giving the value of the constrained sum; see below under details.
...	additional arguments (for example, parameters) passed to the underlying mixing distribution when <code>rmix</code> or <code>qmix</code> is a <code>character</code> string or <code>function</code> .

## Details

Internally used is `factor`, so `scale` is not required to be provided if `factor` is given.

The default factorization used to obtain `factor` is the Cholesky decomposition via `chol()`. To this end, `scale` needs to have full rank.

Sampling from a singular normal variance mixture distribution can be achieved by providing `factor`. The number of rows of `factor` equals the dimension  $d$  of the sample. Typically (but not necessarily), `factor` is square.

`rStudent()` and `rNorm()` are wrappers of `rnmix(, qmix = "inverse.gamma", df = df)` and `rnmix(, qmix = "constant", df = df)`, respectively.

The function `rNorm_sumconstr()` can be used to sample from the multivariate standard normal distribution under a weighted sum constraint; the implementation is based on Algorithm 1 in Vrnin (2018). Let  $Z = (Z_1, \dots, Z_d) \sim N_d(0, I_d)$ . The function `rNorm_sumconstr()` then samples from  $Z | w^T Z = s$  where  $w$  and  $s$  correspond to the arguments `weights` and `s`. If supplied `s` is a vector of length `n`, the  $i$ 'th row of the returned matrix uses the constraint  $w^T Z = s_i$  where  $s_i$  is the  $i$ 'th element in `s`.

## Value

`rnmix()` returns an  $(n, d)$ -matrix containing  $n$  samples of the specified (via `mix`)  $d$ -dimensional multivariate normal variance mixture with location vector `loc` and scale matrix `scale` (a covariance matrix).

`rStudent()` returns samples from the  $d$ -dimensional multivariate Student  $t$  distribution with location vector `loc` and scale matrix `scale`.

`rNorm()` returns samples from the  $d$ -dimensional multivariate normal distribution with mean vector `loc` and covariance matrix `scale`.

`rNorm_sumconstr()` returns samples from the  $d$ -dimensional multivariate normal distribution conditional on the weighted sum being constrained to `s`.

**Examples**

```
### Examples for rnmix() #####

## Generate a random correlation matrix in d dimensions
d <- 3
set.seed(157)
A <- matrix(runif(d * d), ncol = d)
P <- cov2cor(A %*% t(A))

## Draw random variates and compare
df <- 3.5
n <- 1000
set.seed(271)
X <- rnmix(n, rmix = "inverse.gamma", df = df, scale = P) # with scale
set.seed(271)
X. <- rnmix(n, rmix = "inverse.gamma", df = df, factor = t(chol(P))) # with factor
stopifnot(all.equal(X, X.))

## Checking df = Inf
set.seed(271)
X <- rnmix(n, rmix = "constant", scale = P) # normal
set.seed(271)
X. <- rnmix(n, rmix = "inverse.gamma", scale = P, df = Inf) # t_infinity
stopifnot(all.equal(X, X.))

## Univariate case (dimension = number of rows of 'factor' = 1 here)
set.seed(271)
X.1d <- rnmix(n, rmix = "inverse.gamma", df = df, factor = 1/2)
set.seed(271)
X.1d. <- rnmix(n, rmix = "inverse.gamma", df = df, factor = 1)/2 # manual scaling
stopifnot(all.equal(X.1d, X.1d.))
```

```

## Checking different ways of providing 'mix'
## 1) By providing a character string (and corresponding ellipsis arguments)
set.seed(271)
X.mix1 <- rnmix(n, rmix = "inverse.gamma", df = df, scale = P)
## 2) By providing a list; the first element has to be an existing distribution
## with random number generator available with prefix "r"
rinverse.gamma <- function(n, df) 1 / rgamma(n, shape = df/2, rate = df/2)
set.seed(271)
X.mix2 <- rnmix(n, rmix = list("inverse.gamma", df = df), scale = P)
## 3) The same without extra arguments (need the extra list() here to
## distinguish from Case 1))
rinverseGamma <- function(n) 1 / rgamma(n, shape = df/2, rate = df/2)
set.seed(271)
X.mix3 <- rnmix(n, rmix = list("inverseGamma"), scale = P)
## 4) By providing a quantile function
## Note:  $P(1/Y \leq x) = P(Y \geq 1/x) = 1 - F_Y(1/x) = y \Leftrightarrow x = 1/F_Y^{-(1-y)}$ 
set.seed(271)
X.mix4 <- rnmix(n, qmix = function(p) 1/qgamma(1-p, shape = df/2, rate = df/2),
               scale = P)
## 5) By providing random variates
set.seed(271) # if seed is set here, results are comparable to the above methods
W <- rinverse.gamma(n, df = df)
X.mix5 <- rnmix(n, rmix = W, scale = P)
## Compare (note that X.mix4 is not 'all equal' with X.mix1 or the other samples)
## since rgamma() != qgamma(runif()) (or qgamma(1-runif()))
stopifnot(all.equal(X.mix2, X.mix1),
          all.equal(X.mix3, X.mix1),
          all.equal(X.mix5, X.mix1))

## For a singular normal variance mixture:
## Need to provide 'factor'
A <- matrix( c(1, 0, 0, 1, 0, 1), ncol = 2, byrow = TRUE)
stopifnot(all.equal(dim(rnmix(n, rmix = "constant", factor = A)), c(n, 3)))
stopifnot(all.equal(dim(rnmix(n, rmix = "constant", factor = t(A))), c(n, 2)))

## Using 'skip'. Need to reset the seed everytime to get the same shifts in "sobol".
## Note that when using method = "sobol", we have to provide 'qmix' instead of 'rmix'.
set.seed(271)
X.skip0 <- rnmix(n, qmix = "inverse.gamma", df = df, scale = P, method = "sobol")
set.seed(271)
X.skip1 <- rnmix(n, qmix = "inverse.gamma", df = df, scale = P, method = "sobol",
               skip = n)
set.seed(271)
X.wo.skip <- rnmix(2*n, qmix = "inverse.gamma", df = df, scale = P, method = "sobol")
X.skip <- rbind(X.skip0, X.skip1)
stopifnot(all.equal(X.wo.skip, X.skip))

### Examples for rStudent() and rNorm() #####

## Draw  $N(0, P)$  random variates by providing scale or factor and compare
n <- 1000

```

```

set.seed(271)
X.n <- rNorm(n, scale = P) # providing scale
set.seed(271)
X.n. <- rNorm(n, factor = t(chol(P))) # providing the factor
stopifnot(all.equal(X.n, X.n.))

## Univariate case (dimension = number of rows of 'factor' = 1 here)
set.seed(271)
X.n.1d <- rNorm(n, factor = 1/2)
set.seed(271)
X.n.1d. <- rNorm(n, factor = 1)/2 # manual scaling
stopifnot(all.equal(X.n.1d, X.n.1d.))

## Draw t_3.5 random variates by providing scale or factor and compare
df <- 3.5
n <- 1000
set.seed(271)
X.t <- rStudent(n, df = df, scale = P) # providing scale
set.seed(271)
X.t. <- rStudent(n, df = df, factor = t(chol(P))) # providing the factor
stopifnot(all.equal(X.t, X.t.))

## Univariate case (dimension = number of rows of 'factor' = 1 here)
set.seed(271)
X.t.1d <- rStudent(n, df = df, factor = 1/2)
set.seed(271)
X.t.1d. <- rStudent(n, df = df, factor = 1)/2 # manual scaling
stopifnot(all.equal(X.t.1d, X.t.1d.))

## Check df = Inf
set.seed(271)
X.t <- rStudent(n, df = Inf, scale = P)
set.seed(271)
X.n <- rNorm(n, scale = P)
stopifnot(all.equal(X.t, X.n))

### Examples for rNorm_sumconstr() #####
set.seed(271)
weights <- c(1, 1)
Z.constr <- rNorm_sumconstr(n, weights = c(1, 1), s = 2)
stopifnot(all(rowSums(Z.constr ) == 2))
plot(Z.constr , xlab = expression(Z[1]), ylab = expression(Z[2]))

```

**Description**

Sampling and density evaluation for the multivariate skew-t distribution and copula.

**Usage**

```
rskewt(n, loc = rep(0, d), scale = diag(2), factor = NULL, gamma = rep(0, d),
      df = Inf, method = c("PRNG", "sobol", "ghalton"), skip = 0)
dskewt(x, loc = rep(0, d), scale = diag(2), gamma = rep(0, d), df,
      log = FALSE, scale.inv, ldet)

rskewtcopula(n, scale = diag(2), factor = NULL, gamma = rep(0, d), df = Inf,
            pseudo = TRUE, method = c("PRNG", "sobol", "ghalton"), skip = 0)
dskewtcopula(u, scale = diag(2), gamma = rep(0, d), df, log = FALSE,
            scale.inv, ldet)
```

**Arguments**

<code>u</code>	$(n, d)$ -matrix of evaluation points or data; Have to be in $(0, 1)$ .
<code>x</code>	$(n, d)$ -matrix of evaluation points or data
<code>n</code>	sample size $n$ (positive integer).
<code>df</code>	positive degrees of freedom; can also be <code>Inf</code> in which case the copula is interpreted as the Gaussian copula.
<code>loc</code>	location of length $d$ .
<code>gamma</code>	Skewness-vector of dimension $d$ ; if all $(\text{gamma} == 0)$ , the classical $t$ distribution or copula results.
<code>scale</code>	scale matrix (a covariance matrix entering the distribution as a parameter) of dimension $(d, d)$ (defaults to $d = 2$ ). Note that <code>scale</code> must be positive definite,
<code>factor</code>	$(d, d)$ -matrix such that <code>factor %*% t(factor)</code> equals <code>scale</code> . If not provided, <code>factor</code> is internally determined via <code>chol()</code>
<code>scale.inv</code>	inverse of <code>scale</code> ; if not provided, computed via <code>pd.solve(scale)</code> .
<code>ldet</code>	<code>log(det(scale))</code> ; if not provided, computed via <code>pd.solve(scale)</code> .
<code>log</code>	<b>logical</b> indicating whether the logarithmic density is to be computed.
<code>pseudo</code>	<b>logical</b> ; if <code>TRUE</code> , copula samples are computed via <code>pobs()</code> from a multivariate skew- $t$ sample. If <code>FALSE</code> , the univariate skew $t$ distribution functions are internally approximated via <code>integrate()</code> ; see details below.
<code>method</code>	see <code>rnmix()</code> .
<code>skip</code>	see <code>rnmix()</code> .

**Details**

Functionalities for sampling from the multivariate skew- $t$  distribution and copula; the former has stochastic representation  $\mu + W\gamma + \sqrt{W}AZ$  where  $AA^T = \text{scale}$ ,  $W$  follows an inverse-gamma distribution with parameters  $\text{df}/2$  and is independent of the  $d$ -dimensional vector  $Z$  following a standard multivariate normal distribution. When  $\text{gamma}$  is the null-vector, the distribution becomes the multivariate  $t$  distribution.

A major computational challenge when working with the skew  $t$  copula is the lack of an available distribution and quantile function of the univariate skew  $t$  distribution. These are required in

rskewtcopula(, pobs = FALSE) and in dskewtcopula(). The univariate skew  $t$  distribution and quantile functions are currently implemented as described Yoshiba, T. (2018).

The functions described here are currently being further developed to improve stability, accuracy and speed, so that arguments may change in subsequent versions of nvmix.

### Value

$n$ -vector of (log-)density values and  $(n, d)$ -matrix of samples, respectively.
